The figure displays a 10x10 grid of small plots, each showing the distribution of points for a specific value of α . The plots are arranged in a grid where the top row represents $\alpha = 0$ and the bottom row represents $\alpha = 1$. The columns represent different values of α from 0 to 1. The plots show a transition from a uniform distribution of points at $\alpha = 0$ to a highly concentrated distribution of points in the center of the grid at $\alpha = 1$. The points are represented by small black dots, and the background is a light gray grid.

Figure 1. The effect of the concentration of the *Agrobacterium* suspension on the transformation efficiency of *Agrobacterium* strains. The number of transformed cells was determined by the number of colonies obtained on the selective medium. The results are the mean of three independent experiments. Error bars represent standard deviation.

It is important to note that the above results are based on the assumption that the data are normally distributed. If the data are not normally distributed, the results may be biased. Therefore, it is important to check the normality of the data before using the above methods.

Figure 1. The effect of the initial concentration of the monomer on the polymerization of α -methylstyrene initiated by BuLi in THF at -78°C . The polymerization was carried out in the presence of 1.0×10^{-2} mole/l. of BuLi in THF at -78°C . The polymerization was terminated by the addition of 10% aqueous HCl . 1. *Phragmites* (reed) beds are the most common wetland type in the study area, covering 45% of the total area. They are characterized by dense stands of tall, narrow-leaved grasses that grow in shallow water or saturated soil. Reed beds provide important habitat for waterfowl and other wildlife, and they also play a role in water filtration and sediment trapping.

Figure 1. The effect of the concentration of the *Agrobacterium* suspension on the transformation efficiency of *Agrobacterium* strains. The *Agrobacterium* strains were grown in the YEA medium for 24 h at 28 °C. The cell concentration of the strains was adjusted to 10⁸ cells/ml. The cell suspension was mixed with the plant tissue and incubated for 24 h at 28 °C. The plant tissue was then cultured on the selective medium. The transformation efficiency was determined as the number of transformants per 100 mg of plant tissue. The data are the mean ± SD of three independent experiments.

The number of correct responses generally increased with the number of trials, indicating that participants improved their performance as they practiced the task.

Figure 1 shows a schematic diagram of a 2D hexagonal lattice. The lattice is composed of blue circles representing atoms. A central atom is highlighted with a larger blue circle. A red arrow points from this central atom to a neighboring atom, representing a displacement vector. The lattice is labeled with 'a' for the lattice constant and 'r' for the distance from the center to a lattice site.
